Group 4
A method of human resource development to effectively utilize the Integrated Expert System
Francisco RIOS (CISMID, UNI)
Takuya NAGAE (Nagoya University)
OBJECTIVES

4-1 **Enhance the capabilities of stakeholders and governmental officers to use the integrated expert system, under pre-disaster and post-disaster.**

4-2 **Awareness of the local government by promoting a sensibilization campaign in the most expected damaged sectors in the target area.**

4-3 **Awareness the community by the use of easy tools to alert at what level of risk they are exposed, if a big earthquake occurs.**

Integrating Expert System

*Functions consisting of Expert System will be demonstrated, given the representation of entire system design.
*Integrating Expert System will be used from 2025.

El investigador principal, la Universidad Nacional de Ingeniería (UNI) del Perú, Ingeniería (UNI) del Perú tiene un convenio integral con ellos.
Resulta bastante difícil continuar con las actividades educativas si de repente hay una pequeña brecha.

The purpose is disaster risk management. One of the major points is to develop human resources for disaster prevention personnel. It will be developed for those who mainly use the expert system, or for persons who need to make administrative decisions towards those who evacuate.

Regarding the expert system developed this time, such people will be trained to understand how to use it and what can be done with it.

There are INDECI and CENEPRED in Peruvian side. So, it's reasonable proceed with education activities together.

Raising the awareness of disaster prevention among the general public is targeted. For example, introductory videos and comprehensible texts will be produced.

G4 Prof. Tanaka, Tokoha University

(1) Training for experts (users), and (2) Workshop or seminar for citizens have been conducted.

Reviewing the past SATREPS projects, the ideas were indicated regarding the earthquake disaster prevention for our Group 4.

First is a field survey that investigated the needs revealing what is necessary, or what is missing.

After developing a corresponding system for it, training will be performed on-site. Basically produced will be education materials and seminars and workshops may be held for the presentations on the results of training.

After that, such training systems will be taken over to the communities to use it continuously.

The first seminar can be held with Japanese tools, and after that, such mechanism will be taken over by the peruvian counterpart to continue.
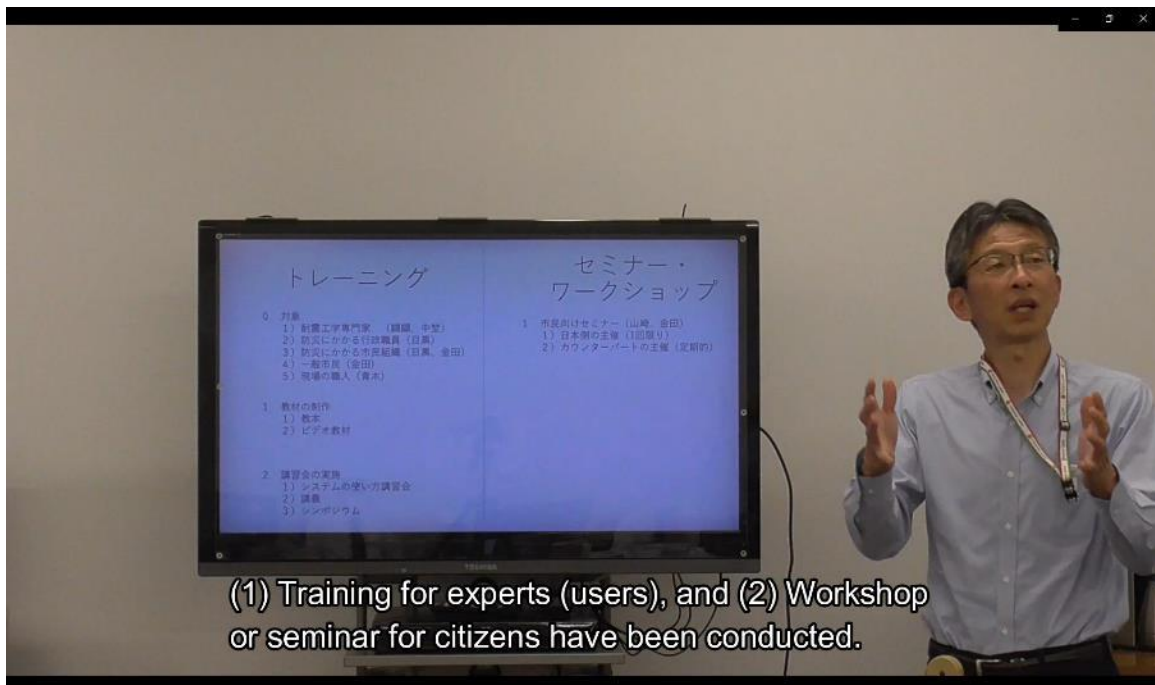

Strategy using Science Literacy;
**Education programs** will be proposed with a series of the discipline explanation tools.

⬇

That is because education effects are well enhanced by the understanding process of the disciplines.

⬇

The disciplines are the outcomes from each group.

As the investigations of groups 1, 2 and 3 are developed, training activities will be developed through training and seminars for officials of the entities involved including officers from local Municipalities, so that they can learn the scientific basis of the project.

A famous training evaluation methods

Kirkpatrick's four-point evaluation is commonly used as a conventional training evaluation method. Developed in 1959, it has been widely used in Japan and overseas.

- Level 1 measures satisfaction immediately after training. Evaluated subjectively by participants.

- Level 2 allows objective evaluation by a third party, such as judging the degree of learning achievement based on reports and tests immediately after training.

- Level 3 verifies whether behavioral changes have occurred in daily work due to the effects of the training after completing the training. Evaluation will be conducted through interviews with trainees and interviews with superiors.

- Level 4 examines how the training impacted performance. Evaluate whether the training has created value for the organization as a whole, for example, increased productivity/increased sales.

Not just training but interactions are important!

National Institute of Civil Defense (INDECI)

- Conducts reactive management processes within the framework of the National Disaster Risk Management System (SINAGERD) for the benefit of the population in general, their livelihoods and the State's assets in an immediate, permanent and efficient manner.

National Center for Disaster Risk Estimation, Prevention and Reduction (CENEPRED)

- Proposes regulations, develop capacities, provide technical assistance and information on prospective and corrective disaster risk management to the members that make up the SINAGERD, in a timely and reliable manner, to reduce the vulnerability of the population and their livelihoods to the risk of disasters.

There are 5 dynamic actuators in each of the 2 horizontal directions, and 14 actuators in the vertical direction.

The nickname of the 3-D Full-Scale Earthquake Testing Facility is E-Defense. The location is Miki City of Hyogo Prefecture. It's located in the Miki Disaster Management Park. The cost to make this was 45 billion yen (350million USD).

This international facility is the biggest shaking table with the highest performance. And also this shaking table facility can reproduce long-period, long-duration earthquakes that caused damage in the Great East Japan Earthquake.

This is the basic specification of the E-Defense facility. With the maximum accommodating weight of 1200 tons, a 6-story reinforced concrete building in Japan, or a slightly slimmer 10-story reinforced concrete building can be tested.

We look forward to working with you in this SATREPS project.
The large-scale test specimen adopted 10-story steel frame structure with an aluminum curtain wall installed. The plane is 12m x 8m. It's 27m in height. The total weight of the test specimen is 550 tons.

In preparation for future earthquakes, it is essential to promote measures to maintain the function of building structures and to continue the public daily life and the nation economic activities.

The dynamic characteristics of the structure, such as the natural period and the damping ratio, are very important for the countermeasure planning, but the method for obtaining them accurately has not yet been established.

The purpose of this research is to develop and demonstrate the technologies to evaluate the dynamic characteristics of the structures and utilize them for the various earthquake countermeasures.
